

UC2 – Cloud Log Monitoring & Visualization

This is technically different from the other CRUD applications. The source describes capturing logs, sending them to a cloud service, visualizing them and setting alert thresholds, with centralized logging, real-time viewing and error alerts.

Student	PPT Presentation	MVP Demonstration
S1	Problem → developers' monitoring challenge → proposed solution	Open monitoring dashboard and show overall status
S2	Dashboard/UI → log views → filters/visualization	Filter/view logs and demonstrate dashboard
S3	Log generation/application logic → log flow	Generate an application event/error and show resulting log
S4	Log data → structure → processing/analysis	Show log entry being captured, filtered or categorized
S5	Cloud/GCP architecture → cloud logging implementation	Show logs arriving in the cloud service and dashboard
S6	Networking/deployment → application-to-cloud log flow	Demonstrate deployed application/resource generating logs
S7	Alerts/optimization/advanced visualization	Trigger an error/threshold and demonstrate alert
S8	Testing → error scenarios → system health/impact	Generate an intentional error and show detection/alert

Important: For UC2, S4 should not artificially present an SQLite database if the team's actual solution does not use one.
